2.0 CLASSICAL MECHANICS

2.1 FUNDAMENTAL TECHNIQUES

2.1.1 The Virial Theorem

The equation of motion of a system can be written in the form
\[ \ddot{F}_i - \ddot{p}_i = 0. \] (2.1)

We are interested in the quantity
\[ G = \sum_i \ddot{p}_i \cdot \ddot{\eta}. \] (2.2)

Differentiating this expression gives
\[ \frac{dG}{dt} = \sum_i \dddot{\eta} \cdot \ddot{p}_i + \sum_i \dddot{p}_i \cdot \ddot{\eta} = \sum_i m_i \dddot{\eta} \cdot \ddot{\eta} + \sum_i \dddot{p}_i \cdot \ddot{\eta}. \] (2.3)

From Equation 2.1 this reduces to
\[ \frac{dG}{dt} = 2T + \sum_i \dddot{F}_i \cdot \dddot{\eta}. \] (2.4)

Averaging over a period of time \( \tau \), we obtain
\[ \frac{1}{\tau} \int_0^\tau \frac{dG}{dt} dt = \frac{1}{\tau} [G(\tau) - G(0)] = \langle 2T \rangle + \left\langle \sum_i \dddot{F}_i \cdot \dddot{\eta} \right\rangle. \] (2.5)

If the motion is periodic, with \( \tau = \) period, then the left hand side of Equation 2.5 is zero and we see that
\[ \langle T \rangle = - \frac{1}{2} \left\langle \sum_i \dddot{F}_i \cdot \dddot{\eta} \right\rangle. \] (2.6)
2.1.2 D’Alembert’s Principle

From Equation 2.1 it follows that the virtual work done by this system is also zero,

$$\sum_i \left( \vec{F}_i - \dot{\vec{p}}_i \right) \cdot \delta \vec{r}_i = 0. \quad (2.7)$$

The total force will be a combination of externally applied forces and internal constraints,

$$\vec{F}_i = \vec{F}_i^{\alpha} + \vec{f}_i, \quad (2.8)$$

so that Equation 2.8 reduces to

$$\sum_i \left( \vec{F}_i^{\alpha} - \dot{\vec{p}}_i \right) \cdot \delta \vec{r}_i - \sum_i \vec{f}_i \cdot \delta \vec{r}_i = 0. \quad (2.9)$$

If we restrict our attention to rigid bodies and other systems for which the forces of constraint do no work then we conclude that the condition for equilibrium of a system is given by D’Alembert’s principle which states

$$\sum_i \left( \vec{F}_i^{\alpha} - \dot{\vec{p}}_i \right) \cdot \delta \vec{r}_i = 0. \quad (2.10)$$

2.1.3 Lagrange’s Equation

If $\vec{r}_i$ is a function of independent variables $q_j$, then

$$\delta \vec{r}_i = \sum_j \frac{\partial \vec{r}_i}{\partial q_j} \delta q_j. \quad (2.11)$$

Dropping the superscript "$\alpha$" for convenience, the first term from Equation 2.10 is

$$\sum_i \vec{F}_i \cdot \delta \vec{r}_i = \sum_{i,j} \vec{F}_i \cdot \frac{\partial \vec{r}_i}{\partial q_j} \delta q_j = \sum_j Q_j \delta q_j. \quad (2.12)$$
where \( Q_j \) is the generalized force. The second term in Equation 2.10 is

\[
\sum_i \hat{p}_i \cdot \delta \hat{r}_i = \sum_i m_i \hat{r}_i \cdot \delta \hat{r}_i = \sum_{i,j} m_i \hat{r}_i \cdot \frac{\partial \hat{r}_j}{\partial q_j} \delta q_j.
\] (2.13)

By definition

\[
\sum_i m_i \hat{r}_i \cdot \frac{\partial \hat{r}_j}{\partial q_j} = \sum_i \left( \frac{d}{dt} \left( m_i \hat{r}_i \cdot \frac{\partial \hat{r}_j}{\partial q_j} \right) - m_i \hat{r}_i \cdot \frac{\partial \hat{r}_j}{\partial q_j} \right).
\] (2.14)

and

\[
\frac{d}{dt} \left( \frac{\partial \hat{r}_j}{\partial q_j} \right) = \frac{\partial \hat{v}_j}{\partial q_j}.
\] (2.15)

Similarly

\[
v_i = \sum_k \frac{\partial \hat{r}_j}{\partial q_k} \hat{q}_k + \frac{\partial \hat{r}_j}{\partial t}
\] (2.16)

so it follows that

\[
\frac{\partial \hat{v}_j}{\partial q_j} = \frac{\partial \hat{r}_j}{\partial q_j}.
\] (2.17)

Using Equations 2.15 and 2.17 in Equation 2.14 we find that

\[
\sum_i m_i \hat{r}_i \cdot \frac{\partial \hat{r}_j}{\partial q_j} = \sum_i \left( \frac{d}{dt} \left( m_i \hat{v}_i \cdot \frac{\partial \hat{r}_j}{\partial q_j} \right) - m_i \hat{v}_i \cdot \frac{\partial \hat{r}_j}{\partial q_j} \right).
\] (2.18)

Equations 2.12 and 2.18 are combined to give

\[
\sum_j \left( \frac{d}{dt} \left( \frac{\partial}{\partial q_j} \left( \sum_i \frac{1}{2} m_i \nu_i^2 \right) \right) - \frac{\partial}{\partial q_j} \left( \sum_i \frac{1}{2} m_i \nu_i^2 \right) - Q_j \right) \delta q_j = 0,
\] (2.19)
or

$$\sum_{j} \left( \frac{d}{dt} \left( \frac{\partial T}{\partial q_j} \right) - \frac{\partial T}{\partial q_j} \right) - Q_j \delta q_j = 0. \quad (2.20)$$

Consequently,

$$\left( \frac{d}{dt} \left( \frac{\partial T}{\partial q_j} \right) - \frac{\partial T}{\partial q_j} \right) = Q_j. \quad (2.21)$$

If $F_i = -\nabla V_i$, then

$$Q_j = \sum_i \ddot{q}_i \frac{\partial \ddot{q}_i}{\partial q_j} = - \sum_i \nabla_i V \cdot \frac{\partial \ddot{q}_i}{\partial q_j} = - \frac{\partial V}{\partial q_j}. \quad (2.22)$$

Equation 2.21 is equivalent to

$$\left( \frac{d}{dt} \left( \frac{\partial T}{\partial q_j} \right) - \frac{\partial}{\partial q_j} (T - V) \right) = 0. \quad (2.23)$$

We define $L = T - V$ to be the Lagrangian. If $V$ is not a function of time then

$$\left( \frac{d}{dt} \left( \frac{\partial L}{\partial q_j} \right) - \frac{\partial L}{\partial q_j} \right) = 0. \quad (2.24)$$

which is known as Lagrange's equation, can be used to determine the equations of motion. We also define

$$p_j = \frac{\partial L}{\partial \dot{q}_j}, \quad (2.25)$$

to be the canonical, or conjugate, momentum. If the Lagrangian does not contain a given coordinate $q_j$ then the coordinate is said to be cyclic or ignorable.
2.1.3.1 The Two Body Central Force Problem

As an example of the application of Lagrange's equation, consider a system of two mass points \( m_1 \) and \( m_2 \) subject to an interaction potential \( V \), where \( V \) is any function of the vector between the particles. The kinetic energy is

\[
T = \frac{1}{2} m_1 \dot{r}_1^2 + \frac{1}{2} m_2 \dot{r}_2^2. \tag{2.26}
\]

The kinetic energy can also be written as the kinetic energy of the center of mass plus the kinetic energy about the center of mass. We define \( \vec{R} \) = position of the center of mass, and \( \vec{r} = \vec{r}_1 - \vec{r}_2 = \) vector between \( m_1 \) and \( m_2 \). The kinetic energy of the center of mass is given by

\[
T_{cm} = \frac{1}{2} (m_1 + m_2) \dot{R}^2. \tag{2.27}
\]

Relative to the center of mass, the position of \( m_1 \) and \( m_2 \) are given by

\[
\vec{r}_1' = \frac{-m_2}{m_1 + m_2} \vec{r}, \tag{2.28}
\]

and

\[
\vec{r}_2' = \frac{m_1}{m_1 + m_2} \vec{r}. \tag{2.29}
\]

Therefore, the kinetic energy about the center of mass is given by

\[
T' = \frac{1}{2} m_1 \dot{r}_1'^2 + \frac{1}{2} m_2 \dot{r}_2'^2 = \frac{1}{2} \left( \frac{m_1 m_2}{m_1 + m_2} \right) \dot{r}^2. \tag{2.30}
\]

Consequently, the Lagrangian is

\[
L = \frac{1}{2} (m_1 + m_2) \dot{R}^2 + \frac{1}{2} \left( \frac{m_1 m_2}{m_1 + m_2} \right) \dot{r}^2 - V(r, \dot{r}, \ldots). \tag{2.31}
\]

We see immediately that because the potential is only a function of the vector between the particles the conjugate momentum of \( \vec{R} \), (the momentum of the center of mass), is constant. That is, the motion of the center of mass has no
effect on the motion about the center of mass. This also implies that there will be no out of plane motion.

2.1.3.2 The Inverse Square Law of Forces

When \( V \) is a function of \( r \) only, as is the case for gravitational or electrostatic forces, Equation 2.31 may be expressed in polar coordinates as

\[
L = \frac{1}{2} \mu \left( r^2 + r^2 \dot{\theta}^2 \right) - V(r). \tag{2.32}
\]

Note that we have chosen to ignore the term describing the motion of the center of mass since it has no effect on other parameters and we have introduced the definition

\[
\mu = \frac{m_1 m_2}{m_1 + m_2}, \tag{2.33}
\]

where \( \mu \) is termed the reduced mass. The equations of motion are found from Lagrange’s equation, (Equation 2.24). For the variable \( q = \theta \) we have

\[
\frac{d}{dt} \left( \frac{\partial L}{\partial \dot{\theta}} \right) - \frac{\partial L}{\partial \theta} = \frac{d}{dt} (\mu \dot{\theta}) = 0, \tag{2.34}
\]

while for \( q = r \) we have

\[
\frac{d}{dt} \left( \frac{\partial L}{\partial \dot{r}} \right) - \frac{\partial L}{\partial r} = \mu \ddot{r} - \mu \dot{\theta}^2 + \frac{\partial V}{\partial r} = 0. \tag{2.35}
\]

For many problems of interest, such as orbital mechanics, \( m_1 \gg m_2 \) and \( \mu \rightarrow m_2 \). The physical consequence is that the smaller particle, \( m_2 \), is subjected to the largest perturbation in its motion. From this point forward we will follow the usual convention and replace \( \mu \) with the symbol \( m \) with the understanding that it refers to the motion of the smaller of \( m_1 \) and \( m_2 \) about the center of mass.

Equation 2.34 is the statement of conservation of angular momentum. That is,

\[
l = mr^2 \dot{\theta}, \tag{2.36}
\]
is a constant. Equation 2.36 can be rewritten in the form

\[ l dt = mr^2 d\theta, \quad (2.37) \]

which implies

\[ \frac{d}{dt} = \frac{l}{mr^2} \frac{d}{d\theta}, \quad (2.38) \]

and

\[ \frac{d^2}{dt^2} = \frac{l}{mr^2} \frac{d}{d\theta} \left( \frac{l}{mr^2} \frac{d}{d\theta} \right). \quad (2.39) \]

The area swept out by a moving body is given by

\[ A = \frac{1}{2} r(\theta). \quad (2.40) \]

It follows that

\[ \frac{dA}{dt} = \frac{l}{mr^2} \frac{d}{d\theta} \left[ \frac{1}{2} r(\theta) \right] = \frac{l}{2}. \quad (2.41) \]

Because angular momentum is conserved \( dA/dt \) is also constant. This is Kepler's Second Law which states that the planets sweep out equal areas in equal times.

From the definition of \( l \), equation 2.35 becomes

\[ m\ddot{r} - \frac{l^2}{mr^3} = -\frac{\partial V}{\partial r}, \quad (2.42) \]

or, because \( V \) is only a function of \( r \),

\[ m\ddot{r} = -\frac{d}{dr} \left( V + \frac{1}{2} \frac{l^2}{mr^2} \right). \quad (2.43) \]
The particle moves in an effective potential given by

$$V_{\text{eff}} = \left( V + \frac{l^2}{2mr^2} \right).$$  \hspace{1cm} (2.44)

Equation 2.43 reduces to

$$m\dot{r} = -\frac{dV_{\text{eff}}}{dr},$$  \hspace{1cm} (2.45)

thus

$$m\ddot{r} = \frac{d}{dt} \left( \frac{1}{2} mr^2 \right) = -\frac{dr}{dt} \frac{dV_{\text{eff}}}{dr} = -\frac{dV_{\text{eff}}}{dt}. \hspace{1cm} (2.46)$$

Consequently,

$$\frac{d}{dt} \left( \frac{1}{2} mr^2 + V_{\text{eff}} \right) = 0,$$  \hspace{1cm} (2.47)

which is the statement that energy is conserved. From this equation, we also find that

$$\dot{r} = \pm \sqrt{\frac{2}{m} \left( E - V_{\text{eff}} \right)} = \pm \sqrt{\frac{2}{m} \left( E - V - \frac{l^2}{2mr^2} \right)},$$  \hspace{1cm} (2.48)

or simply

$$dt = \frac{dr}{\sqrt{\frac{2}{m} \left( E - V - \frac{l^2}{2mr^2} \right)}}. \hspace{1cm} (2.49)$$

Substituting the relation between $dt$ and $d\theta$, Equation 2.37, and we find that

$$d\theta = -\frac{1}{\sqrt{\frac{2mE}{l^2} - \frac{2mV}{l^2} - \frac{1}{r^2}}} \frac{dr}{r^2}. \hspace{1cm} (2.50)$$
Consider the case when the potential is of the form $V = -\frac{k}{r} = -ku$. Equation 2.50 becomes

$$d\theta = \frac{-1}{\sqrt{\frac{2mE}{l^2} + \frac{2mk}{l^2} - u - u^2}} du. \quad (2.51)$$

Integrating this expression gives

$$\theta_f - \theta_i = \arcsin\left(\frac{-2u + \frac{2mk}{l^2}}{\sqrt{\frac{8mE}{l^2} + \left(\frac{2mk}{l^2}\right)^2}}\right) = \arcsin\left(\frac{1 - \frac{l^2}{mk}}{\frac{1}{r}}\right). \quad (2.52)$$

Inverting this expression gives

$$\frac{1}{r} = \frac{mk}{l^2} \left[1 - \sqrt{1 + \frac{2E l^2}{mk^2}} \sin(\theta_f - \theta_i)\right]. \quad (2.53)$$

This is usually written in the form

$$\frac{1}{r} = \frac{mk}{l^2} \left[1 - e \sin(\theta_f - \theta_i)\right]. \quad (2.54)$$

where

$$e = \sqrt{1 + \frac{2E l^2}{mk^2}}. \quad (2.55)$$

This is the equation for a conic section having several classes of solutions as shown below.

1.) If $e > 1$, and $E > 0$, the orbit is a hyperbola.

2.) If $e = 1$, and $E = 0$, the orbit is a parabola.
3.) If $e < 1$, and $E < 0$, the orbit is an ellipse.

4.) If $e = 0$, and $E = -\frac{mk^2}{2l^2}$, the orbit is a circle.

2.2 VARIATIONAL TECHNIQUES

2.2.1 The Calculus of Variations

Consider a function $f(y, \dot{y}, x)$ defined on a path $y=y(x)$ between $x_1$ and $x_2$ where $\dot{y} = dy/dx$. We wish to find a particular path $y(x)$ such that the integral

$$J = \int_{x_1}^{x_2} f(y, \dot{y}, x)dx,$$  \hspace{1cm} (2.56)

has a stationary value relative to paths differing infinitesimally from the correct function $y(x)$. Since $J$ must have a stationary value for the correct path relative to any neighboring path, the variation must be zero relative to some particular set of neighboring paths. Such a set of paths can be denoted by

$$y(x, \alpha) = y(x, 0) + \alpha \eta(x),$$  \hspace{1cm} (2.57)

where $y(x, 0)$ is the correct path and $\eta(x_1) - \eta(x_2) = 0$. Explicitly,

$$J(\alpha) = \int_{x_1}^{x_2} f(y(x, \alpha), \dot{y}(x, \alpha), x)dx.$$  \hspace{1cm} (2.58)

A necessary condition for a stationary point is

$$\left(\frac{dJ}{d\alpha}\right)_{\alpha=0} = 0.$$  \hspace{1cm} (2.59)

From Equation 2.58
\[
\frac{dJ}{d\alpha} = \int_{x_1}^{x_2} \left( \frac{\partial f}{\partial y} \frac{\partial y}{\partial \alpha} + \frac{\partial f}{\partial \alpha} \frac{\partial y}{\partial \alpha} \right) dx. \tag{2.60}
\]

It is easily seen that

\[
\frac{\partial f}{\partial y} \frac{\partial y}{\partial \alpha} = \frac{\partial f}{\partial \alpha} \frac{\partial^2 y}{\partial x \partial \alpha}, \tag{2.61}
\]

so that

\[
\int_{x_1}^{x_2} \frac{\partial f}{\partial y} \frac{\partial y}{\partial \alpha} dx = \int_{x_1}^{x_2} \frac{\partial f}{\partial y} \frac{\partial^2 y}{\partial x \partial \alpha} dx = \left. \frac{\partial f}{\partial \alpha} \frac{\partial y}{\partial \alpha} \right|_{x_1}^{x_2} - \int_{x_1}^{x_2} \frac{d}{dx} \frac{\partial f}{\partial y} \frac{\partial y}{\partial \alpha} dx. \tag{2.62}
\]

From the boundary conditions, the first term on the right hand side vanishes and Equation 2.60 reduces to

\[
\frac{dJ}{d\alpha} = \int_{x_1}^{x_2} \left( \frac{\partial f}{\partial y} \frac{\partial y}{\partial \alpha} - \frac{\partial f}{\partial \alpha} \frac{\partial y}{\partial \alpha} \right) dx. \tag{2.63}
\]

The fundamental lemma of the calculus of variations states that if

\[
\int_{x_1}^{x_2} M(x) \eta(x) dx = 0, \tag{2.64}
\]

for all \( \eta(x) \) continuous through the second derivative then \( M(x) \) must be identically zero on the interval. Thus \( J \) is stationary only if

\[
\frac{\partial f}{\partial y} - \frac{d}{dx} \left( \frac{\partial f}{\partial y} \right) = 0. \tag{2.65}
\]

If \( f \) is a function of many independent variables then

\[
\frac{\partial f}{\partial y_i} - \frac{d}{dx} \left( \frac{\partial f}{\partial y_i} \right) = 0. \tag{2.66}
\]
2.2.2 Hamilton's Principle

Hamilton's principle states that the motion, in configuration space, of a system where all non-constraining forces are derivable from a generalized scalar potential that may be a function of coordinates, velocities, and time is such that the integral

\[ I = \int_{t_1}^{t_2} L dt, \quad (2.67) \]

has a stationary value for the correct path of the motion. That is,

\[ \delta I = \delta \int_{t_1}^{t_2} L dt = 0. \quad (2.68) \]

The integral \( I \) is termed the action, and Hamilton's principle states that the variation in \( I \) is zero. In other words, the action is minimized. By comparison with Equation 2.65 it follows that

\[ \frac{\partial L}{\partial q_i} - \frac{d}{dt} \frac{\partial L}{\partial \dot{q}_i} = 0, \quad (2.69) \]

which is Lagrange's equation.

2.2.3 Lagrange Multipliers

D'Alemberts principle, and the resulting form of Lagrange's equation, assume no constraint forces. Consider a treatment when the equations of constraint can be put in the form

\[ \sum_k a_{ik} dq_k + a_{il} = 0. \quad (2.70) \]

where the \( a_{ik} \) and \( a_{il} \)'s may be functions of \( a, t \). For virtual displacements it follows that
If this is true, then it must also follow that

$$\lambda_l \sum_k a_{lk} \delta q_k = 0 .$$  \hspace{1cm} (2.72)

where the $\lambda_l$ are undetermined coefficients called Lagrange multipliers. From Equations 2.63, 2.68, and 2.69 it is seen that Hamilton's principle is equivalent to

$$\int \sum_k \left( \frac{\partial L}{\partial q_k} - \frac{d}{dt} \frac{\partial L}{\partial \dot{q}_k} \right) \delta q_k = 0 .$$  \hspace{1cm} (2.73)

By the same process, Equation 2.72 is equivalent to

$$\int \sum_{k,j} \lambda_{lj} a_{ij} \delta q_k dt = 0 .$$  \hspace{1cm} (2.74)

We combine these two relations to obtain

$$\int \sum_{k=1}^n \left( \frac{\partial L}{\partial q_k} - \frac{d}{dt} \frac{\partial L}{\partial \dot{q}_k} + \sum_l \lambda_{lj} a_{lk} \right) \delta q_k dt = 0 .$$  \hspace{1cm} (2.75)

The $\delta q_k$'s are not necessarily independent, but because the values of the $\lambda_l$'s are undetermined we may choose them such that

$$\frac{d}{dt} \left( \frac{\partial L}{\partial \dot{q}_k} \right) - \frac{\partial L}{\partial q_k} = \sum_l \lambda_{lj} a_{lk} .$$  \hspace{1cm} (2.76)

These equations, together with Equation 2.70, can be used to determine the equations of motions for systems with constraining forces.
Example 2.1

Consider the case of a ladder of length $L$ that is inclined against a frictionless wall and floor as shown at right. Find the equations of motion.

The position of the center of mass of the ladder, and its orientation, can be described with the variables $x$, $y$, $\theta$. The motion of the ladder is constrained by the wall and floor. We have the two constraints

$$x = \frac{L}{2} \sin \theta, \quad (2.77)$$

and

$$y = \frac{L}{2} \cos \theta. \quad (2.78)$$

From Equation 2.60 it follows that these give the constraining relations

$$\lambda_1 \left[ dx - \frac{L}{2} \cos \theta d\theta \right] = 0, \quad (2.79)$$

and

$$\lambda_2 \left[ dy + \frac{L}{2} \sin \theta d\theta \right] = 0, \quad (2.80)$$

respectively. By inspection, the kinetic energy is

$$T = \frac{1}{2} m (x^2 + y^2) + \frac{1}{2} I \dot{\theta}^2, \quad (2.81)$$

where $I = \frac{1}{12} m L^2$. Similarly, the potential energy is

$$V = mgy, \quad (2.82)$$
so that the Lagrangian is

\[ L = \frac{1}{2} m \left( \dot{x}^2 + \dot{y}^2 \right) + \frac{mL^2}{24} \dot{\theta}^2 - mgy. \]  \hspace{1cm} (2.83)

From Equations 2.76, 2.79, and 2.80 the equations of motion are

\[ m\ddot{x} = \lambda_1, \]  \hspace{1cm} (2.84)

\[ m\ddot{y} + mg = \lambda_2, \]  \hspace{1cm} (2.85)

and

\[ \frac{mL^2}{24} \ddot{\theta} = -\lambda_1 \left( \frac{L}{2} \cos \theta \right) + \lambda_2 \left( \frac{L}{2} \sin \theta \right). \]  \hspace{1cm} (2.86)

respectively. From Equations 2.77 and 2.78 we see that

\[ \dot{x} = -\frac{L}{2} \sin \theta \dot{\theta}^2 + \frac{L}{2} \cos \theta \dot{\theta}, \]  \hspace{1cm} (2.87)

and

\[ \dot{y} = \frac{L}{2} \cos \theta \dot{\theta}^2 - \frac{L}{2} \sin \theta \dot{\theta}. \]  \hspace{1cm} (2.88)

From Equations 2.84 and 2.87 we see that

\[ \lambda_1 = m \left( -\frac{L}{2} \sin \theta \dot{\theta}^2 + \frac{L}{2} \cos \theta \dot{\theta} \right), \]  \hspace{1cm} (2.89)

while from Equation 2.85 and 2.88 we see that

\[ \lambda_2 = m \left( \frac{L}{2} \cos \theta \dot{\theta}^2 - \frac{L}{2} \sin \theta \dot{\theta} + g \right). \]  \hspace{1cm} (2.90)

When these are combined with Equation 2.86 and simplified we obtain

\[ \frac{1}{6} \ddot{\theta} = \left( -\sin \theta \dot{\theta}^2 + \cos \theta \right)(\cos \theta) - \left( \cos \theta \dot{\theta}^2 - \sin \theta \dot{\theta} + g \right)(\sin \theta), \] \hspace{1cm} (2.91)
which is equivalent to

$$\frac{5}{6} \dot{\theta} = -2 \sin \theta \cos \theta \dot{\theta}^2 - g \sin \theta. \quad (2.92)$$

## 2.2 RIGID BODY MOTION

### 2.2.1 Rotations

A rigid body in space needs 6 independent generalized coordinates to specify its configuration. For example, 3 coordinates are needed to specify the location of the center of mass relative to some external axes and 3 other coordinates are needed to specify the orientation of the body relative to a coordinate system parallel to the external axes. The orientation is specified by stating the direction cosine of the body axes relative to the external axes. That is, if the prime denotes body axes then

$$i' = (i' \cdot i) i + (i' \cdot j) j + (i' \cdot k) k, \quad (2.93)$$

or

$$i' = \alpha_1 \hat{i} + \alpha_2 \hat{j} + \alpha_3 \hat{k}, \quad (2.94)$$

or

$$i' = \cos(i' \cdot i) i + \cos(i' \cdot j) j + \cos(i' \cdot k) k. \quad (2.95)$$

Similarly,

$$\tilde{x}' = \tilde{R} \tilde{x}, \quad (2.96)$$

where

$$\tilde{R} = \begin{pmatrix} \alpha_1 & \alpha_2 & \alpha_3 \\ \beta_1 & \beta_2 & \beta_3 \\ \gamma_1 & \gamma_2 & \gamma_3 \end{pmatrix}. \quad (2.97)$$
Because
\[ \|\tilde{x}\| = \|\hat{x}\|. \]  
(2.98)
we have
\[ \tilde{R}\tilde{R}^t = \tilde{I}, \]  
(2.99)
or
\[ \alpha_1^2 + \beta_1^2 + \gamma_1^2 = 1, \]  
(2.100)
for \( l = 1, 2, 3 \). That is,
\[ x_i' = a_{ij}x_j, \]  
(2.101)
and
\[ x_i'x_i' = a_{ij}a_{ik}x_jx_k = x_i'x_i. \]  
(2.102)
Therefore \( \alpha_j'\alpha_{ik} = 1 \), if \( j = k \), \( \alpha_j\alpha_{ik} = 0 \) otherwise. In two dimensions
\[ \tilde{R} = \begin{pmatrix} \cos \phi & \sin \phi \\ -\sin \phi & \cos \phi \end{pmatrix}. \]  
(2.103)

### 2.2.1.1 General Properties of Rotations

If \( \tilde{G} = \tilde{A}\tilde{F} \) and we transform to a new coordinate system then
\[ \tilde{B}\tilde{G} = \tilde{B}\tilde{A}\tilde{F} = \tilde{B}\tilde{A}\tilde{B}^{-1}\tilde{B}\tilde{F} \]  
we say that \( \tilde{B}\tilde{A}\tilde{B}^{-1} \) is the form of \( \tilde{A} \) in the new coordinate system. \( \tilde{A}' = \tilde{B}\tilde{A}\tilde{B}^{-1} \) defines a similarity transformation. In some coordinate system
\[ \tilde{A}' = \begin{pmatrix} \cos \phi & \sin \phi & 0 \\ -\sin \phi & \cos \phi & 0 \\ 0 & 0 & 1 \end{pmatrix}, \]  
(2.104)
so that \( Tr\tilde{A} = 1 + 2\cos \phi \). This property holds true in all coordinate systems.
Example 2.2

Find the axis of rotation and compute the angle of rotation for

\[
\tilde{R} = \begin{pmatrix}
\frac{3}{4} & \frac{\sqrt{6}}{4} & \frac{1}{4} \\
\frac{1}{4} & \frac{\sqrt{6}}{4} & \frac{\sqrt{6}}{4} \\
-\frac{\sqrt{6}}{4} & \frac{1}{4} & \frac{\sqrt{6}}{4} \\
\frac{1}{4} & -\frac{\sqrt{6}}{4} & \frac{3}{4}
\end{pmatrix}.
\]

It can easily be verified that \( \tilde{R}\tilde{R}^T = I \), so \( \tilde{R} \) satisfies the requirements of a rotation matrix. The axis of rotation can be defined as the direction that any vector which remains unchanged by \( \tilde{R} \) points. That is, if \( \tilde{x} = \tilde{R}\tilde{x} \), then \( \tilde{x} \) is the axis of rotation. We must solve

\[
\begin{pmatrix}
\frac{3}{4} & \frac{\sqrt{6}}{4} & \frac{1}{4} \\
\frac{1}{4} & \frac{\sqrt{6}}{4} & \frac{\sqrt{6}}{4} \\
-\frac{\sqrt{6}}{4} & \frac{1}{4} & \frac{\sqrt{6}}{4} \\
\frac{1}{4} & -\frac{\sqrt{6}}{4} & \frac{3}{4}
\end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix} = \begin{pmatrix} x_1 \\ x_2 \\ x_3 \end{pmatrix},
\]

which gives the equations

\[
3x_1 + \sqrt{6}x_2 + x_3 = 4x_1, \quad (2.106)
\]
\[
-\sqrt{6}x_1 + 2x_2 + \sqrt{6}x_3 = 4x_2, \quad (2.107)
\]
\[
x_1 - \sqrt{6}x_2 + 3x_3 = 4x_3. \quad (2.108)
\]

These three equations can be solved to show that \( x_1 = x_3 \) and \( x_2 = 0 \). The normalized axis of rotation is therefore \( \frac{1}{\sqrt{2}}(1, 0, 1) \). By examination, \( \text{Tr} \; \tilde{R} = 1 + 2 \cos \theta = 2 \), so that \( \theta = 60^\circ \).
2.2.2.2 The Euler Angles

Rather than specify the 9 independent elements of the rotation matrix we may
describe the orientation in terms of 3 Euler angles. For example, rotate the
initial system of axes, \(xyz\), by an angle \(\psi\) counterclockwise about \(z\). This
defines the \(\xi\eta\zeta\) axes. Next rotate about the \(\xi\) axis by an angle \(\theta\) in the
counterclockwise direction. This defines the \(\xi'\eta'\zeta'\) axes. Finally rotate
counterclockwise by an angle \(\phi\) about the \(\zeta'\) axes. This defines the \(\xi'\eta'\zeta'\) axes.

In matrix form

\[
\begin{pmatrix}
  x' \\
  y' \\
  z'
\end{pmatrix} = \begin{pmatrix}
  \bar{A} f
\end{pmatrix},
\]

where

\[
\bar{A} = \bar{B} \bar{C} \bar{D},
\]

and

\[
\bar{B} = \begin{pmatrix}
  \cos \psi & \sin \psi & 0 \\
  -\sin \psi & \cos \psi & 0 \\
  0 & 0 & 1
\end{pmatrix},
\]

\[
\bar{C} = \begin{pmatrix}
  1 & 0 & 0 \\
  0 & \cos \theta & \sin \theta \\
  0 & -\sin \theta & \cos \theta
\end{pmatrix},
\]

\[
\bar{D} = \begin{pmatrix}
  \cos \phi & \sin \phi & 0 \\
  -\sin \phi & \cos \phi & 0 \\
  0 & 0 & 1
\end{pmatrix}.
\]

2.2.2.3 The Cayley-Klein Parameters

Consider a general linear transformation in 2 dimensional space

\[
\bar{u}' = \alpha \bar{u} + \beta \bar{v},
\]

and

\[
\bar{v}' = \alpha \bar{v} + \beta \bar{u}.
\]
\[ \mathbf{V}' = \gamma \mathbf{u} + \delta \mathbf{v}, \]  

(2.115)

where the transformation matrix is

\[ \mathbf{Q} = \begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix}, \]  

(2.116)

Note that \( \alpha, \beta, \gamma, \delta \) may be complex. If we require \( \mathbf{Q} \mathbf{Q}' = I \) and \( |\mathbf{Q}| = +1 \) we find that \( \beta = -\gamma^* \) and \( \delta = \alpha^* \), that is

\[ \mathbf{Q} = \begin{pmatrix} \alpha & \beta \\ -\beta^* & \alpha^* \end{pmatrix}. \]  

(2.117)

Consider a matrix of the form

\[ \mathbf{P} = \begin{pmatrix} z & x - iy \\ x + iy & -z \end{pmatrix}, \]  

(2.118)

such that

\[ \mathbf{P}' = \mathbf{Q} \mathbf{P} \mathbf{Q}'. \]  

(2.119)

The hermitian property and the trace of a matrix are unaffected by similarity transformations. Consequently, \( \mathbf{P}' \) is of the form

\[ \mathbf{P}' = \begin{pmatrix} z' & x' - iy' \\ x' + iy' & -z' \end{pmatrix}. \]  

(2.120)

If we let \( x_+ = x + iy \) and \( x_- = x - iy \), then

\[ \mathbf{P}' = \begin{pmatrix} z' & x_- \\ x_+ & z' \end{pmatrix} = \begin{pmatrix} \alpha & \beta \\ \gamma & \delta \end{pmatrix} \begin{pmatrix} z & x_+ \\ x_- & -z \end{pmatrix} = \begin{pmatrix} \alpha & \beta \\ -\beta & \alpha \end{pmatrix}. \]  

(2.121)

In this way, we may define a 9 element rotation matrix in terms of 4 Cayley-Klein parameters.
2.2.2 The Rate of Change of a Vector

The rate of change of a vector $\vec{r}$ as seen by an observer in the body system of axes will differ from the corresponding change as seen by an observer fixed in space. If the body axes are rotating with angular velocity $\omega$ the general solution is

$$\frac{d\vec{r}}{dt}_{\text{space}} = \left(\frac{d\vec{r}}{dt}\right)_{\text{body}} + \vec{\omega} \times \vec{r}. \quad (2.122)$$

We have

$$\vec{v}_s = \vec{v}_b + \vec{\omega} \times \vec{r}, \quad (2.123)$$

and a successive application of Equation 2.122 gives

$$\vec{a}_s = \vec{a}_b + 2(\vec{\omega} \times \vec{v}_b) + \vec{\omega} \times (\vec{\omega} \times \vec{r}) + \frac{d\vec{\omega}}{dt} \times \vec{r}. \quad (2.124)$$

If the angular velocity of the body is constant Newton's law is

$$\vec{F} = m\vec{a}_s = m\vec{a}_b + 2m(\vec{\omega} \times \vec{v}_b) + m\vec{\omega} \times (\vec{\omega} \times \vec{r}). \quad (2.125)$$

To an observer in the rotating system it appears as though the particle is moving under an effective force

$$\vec{F}_{\text{eff}} = m\vec{a}_b = \vec{F} - 2m(\vec{\omega} \times \vec{v}_b) - m\vec{\omega} \times (\vec{\omega} \times \vec{r}). \quad (2.126)$$

The second term on the right hand side is called the Coriolis force and the last term on the right hand side is called the centrifugal force.
Example 2.3

Show that if a particle is thrown up vertically with initial speed $v_0$ and reached a height $h$, that it will experiment a Coriolis deflection that is opposite in direction, and four times greater in magnitude, than the deflection it would experience if it were dropped at rest from the same maximum height.

The rate of rotation of the Earth, $\omega$, is identical for each scenario. The difference is the initial velocity and position of the particle. From equation 2.126, the Coriolis force is $2(\hat{\omega} \times \vec{v}_b)$. Defining the coordinate axes as shown, we have $\omega_x = \omega_y = 0$ and $\omega_z = \omega$, while $v_x = 0$, $v_y = v \cos \theta$, and $v_z = v \sin \theta$.

As a result,

$$-2(\hat{\omega} \times \vec{v}_b) = +2(\hat{\omega} v \cos \theta) \hat{i} + 2(0) \hat{j} + 2(0) \hat{k},$$

(2.127)

As a result, the acceleration due to the Coriolis force is simply

$$\ddot{x} = 2\omega v \cos \theta.$$  

(2.128)

A body falling under the influence of gravity satisfies the condition

$$v = v(0) - gt,$$

(2.129)

where $v(0)$ is defined as the velocity at time $t = 0$. Substituting this into Equation 2.128 and integrating gives

$$\ddot{x} = 2\omega \cos \theta \left[ v(0)t - \frac{1}{2} gt^2 \right].$$

(2.130)

Integrating a second time gives

$$x = 2\omega \cos \theta \left[ \frac{1}{2} v(0)t^2 - \frac{1}{6} gt^3 \right].$$

(2.131)
To solve the problem at hand, we let $t$ be the time it takes for the particle to complete the trip. The position of the particle at any time is given by

$$h(t) = h(0) + v(0)t - \frac{1}{2} gt^2,$$  \hspace{1cm} (2.132)

In one case, the particle starts at rest, $v(0) = 0$, at height $h$. From the definition of the problem, it can be seen that the time required to complete the drop to the ground is

$$t_1 = \sqrt{\frac{2h}{g}} = \frac{v_o}{g},$$  \hspace{1cm} (2.133)

Consequently, the deflection when dropped from rest at height $h$ is

$$x_1 = 2\omega \cos \theta \left[ -\frac{1}{6} \left( \frac{v_o}{g} \right)^3 - \left( \frac{1}{3} \right) \left( \frac{v_o}{g} \right)^3 g\omega \cos \theta \right].$$  \hspace{1cm} (2.134)

If instead, we let $t_2$ be the time it takes to fall from height $h$, we have $v_i = v_o$ and $t_2 = 2t_1$. The deflection is

$$x_2 = 2\omega \cos \theta \left[ \frac{1}{2} \left( \frac{2v_o}{g} \right)^2 - \frac{1}{6} \left( \frac{2v_o}{g} \right)^3 \right] + \left( \frac{4}{3} \right) \left( \frac{v_o^3}{g^2} \right) \omega \cos \theta.$$  \hspace{1cm} (2.135)

Thus, the deflection when thrown from the ground up is opposite in direction, and four times greater in magnitude, than then deflection when dropped from rest.

### 2.2.3 The Rigid Body Equations of Motion

We have previously seen that the total kinetic energy of a rigid body may be expressed as the sum of the kinetic energy of the entire body as if concentrated at the center of mass, plus the kinetic energy of the motion about the center of mass. If a rigid body moves with one point stationary, the angular momentum about the center of mass is
Since \( r_i \) is a fixed vector in the body

\[
\vec{v}_i = \vec{\omega} \times \vec{r}_i. \tag{2.137}
\]

Thus

\[
\vec{L} = m_i (\vec{r}_i \times (\vec{\omega} \times \vec{r}_i)) = m_i (\vec{\omega} r_i^2 - \vec{r}_i \cdot (\vec{\omega} \times \vec{r}_i)). \tag{2.138}
\]

The \( x \)-component is

\[
L_x = \omega_x m_i (r_i^2 - x_i^2) - \omega_y m_i x_i y_i - \omega_z m_i x_i z_i, \tag{2.139}
\]

or

\[
L_x = I_{xx} \omega_x + I_{xy} \omega_y + I_{xz} \omega_z. \tag{2.140}
\]

We define

\[
I_{jk} = \int_V \rho(\vec{r})(r^2 \delta_{jk} - x_j x_k) dV, \tag{2.141}
\]

to be the inertia tensor so that

\[
\vec{L} = \vec{I} \, \vec{\omega}. \tag{2.142}
\]

The kinetic energy of motion about a point is

\[
T = \frac{1}{2} m_i \vec{v}_i^2 = \frac{1}{2} m_i \vec{\omega} \cdot (\vec{\omega} \times \vec{r}_i), \tag{2.143}
\]

or

\[
T = \vec{\omega} \cdot \vec{L} = \frac{1}{2} \vec{\omega} \cdot \vec{I} \cdot \vec{\omega}. \tag{2.144}
\]
The moment of inertia, $\bar{I}$, about some given axis is related to the moment about a parallel axis through the center of mass. Let the vector from the origin to the center of mass be $\bar{R}$ and let the radii vectors from the origin and the center of mass to the $i$th particle be $\bar{r}_i$ and $\bar{r}_i'$ respectively. That is

$$\bar{r}_i = \bar{R} + \bar{r}_i'. \tag{2.145}$$

The moment of inertia about axis $a$ is

$$I_a = m_i (\bar{r}_i \times \hat{n})^2 = m_i [((\bar{R} + \bar{r}_i') \times \hat{n})]^2. \tag{2.146}$$

or

$$I_a = M (\bar{R} \times \hat{n})^2 + m_i (\bar{r}_i' + \hat{n})^2 + 2m_i (\bar{R} \times \hat{n}) (\bar{r}_i' \times \hat{n}). \tag{2.147}$$

The last term is $2(\bar{R} \times \hat{n}) \cdot (\hat{n} \times m_i \bar{r}_i')$, but $\sum m_i \bar{r}_i' = 0$ and $\bar{I}_b = m_i (\bar{r}_i' \times \hat{n})^2$ so

$$\bar{I}_a = \bar{I}_b + M (\bar{R} \times \hat{n})^2. \tag{2.148}$$

### 2.2.3.1 The Euler Equations and Torque-Free Motion

By definition

$$\left( \frac{d\vec{L}}{dt} \right)_s = \left( \frac{d\vec{L}}{dt} \right)_b + \vec{\omega} \times \vec{L} = \vec{N}. \tag{2.149}$$

In the body system, using $L_i = I_{ii} \omega_i$, we find

$$I_i \frac{d\omega_i}{dt} + \epsilon_{ijk} \omega_j \omega_k I_k = N_i. \tag{2.150}$$
The Euler equations are

\[ I_1 \dot{\omega}_1 - \omega_2 \omega_3 (I_2 - I_3) = N_1, \]  
(2.151)

\[ I_2 \dot{\omega}_2 - \omega_3 \omega_1 (I_3 - I_1) = N_2, \]  
(2.152)

\[ I_3 \dot{\omega}_3 - \omega_1 \omega_2 (I_1 - I_2) = N_3. \]  
(2.153)

The principle axes of a system are those where the tensor \( \tilde{T} \) is diagonal. If this is the case,

\[ T = \frac{L^2}{2 I_1} + \frac{L^2}{2 I_2} + \frac{L^2}{2 I_3}. \]  
(2.154)

Because \( T \) is constant, the relation defines an ellipsoid fixed in the body axes. Because angular momentum is conserved \( \tilde{L} \) must be on a fixed sphere defined by

\[ \tilde{L}^2 = L_1^2 + L_2^2 + L_3^2. \]  
(2.155)

For the given initial conditions, kinetic energy and angular momentum, the path of \( \tilde{L} \) is constrained to be the intersection of the sphere, \( \tilde{L}^2 \), and the ellipsoid, \( T \). If we have a body symmetrical about the \( z \) axis so that \( I_1 = I_2 \) the Euler equations are, in the absence of torque's,

\[ I_1 \dot{\omega}_1 = (I_1 - I_3) \omega_3 \omega_1, \]  
(2.156)

\[ I_2 \dot{\omega}_2 = -(I_1 - I_3) \omega_3 \omega_1, \]  
(2.157)

\[ I_3 \dot{\omega}_3 = 0. \]  
(2.158)

We have \( \omega_3 = \text{constant} \), and

\[ \dot{\omega}_1 = -\Omega \omega_2, \quad \dot{\omega}_2 = \Omega \omega_1, \]  
(2.159)

where

\[ \Omega = \frac{I_3 - I_1}{I_1} \omega_3. \]  
(2.160)
Thus,

\[ \dot{\omega}_1 = -\Omega \omega_1, \]  

which has solutions \( \omega_1 = A \cos \Omega t \) and \( \omega_2 = A \sin \Omega t \). Hence, the total angular velocity is constant in magnitude but precesses with frequency \( \Omega \) about the \( \zeta \)-axis. We may solve for \( A \) and \( \omega_3 \) by noting that

\[ T = \frac{1}{2} I_1 A^2 + \frac{1}{2} I_3 \omega_3^2, \]  

and

\[ L^2 = I_1^2 A^2 + I_3^2 \omega_3^2. \]

### 2.2.3.2 The Heavy Symmetrical Top

Consider a heavy top with a symmetry axis taken to be the \( z \)-axis of the coordinate system fixed in the body as shown. The 3 Euler angles are: \( \theta = \) inclination of the \( z \)-axis from the vertical, \( \phi = \) azimuth of the top about the vertical, and \( \psi = \) rotation angle of the top about its own \( z \)-axis. The kinetic energy is

\[ T = \frac{1}{2} I_1 (\dot{\omega}_1^2 + \omega_2^2) + \frac{1}{2} I_3 \omega_3^2, \]

or

\[ T = \frac{1}{2} I_1 (\dot{\theta}^2 + \dot{\phi}^2 \sin^2 \theta) + \frac{1}{2} I_3 (\dot{\psi} + \dot{\phi} \cos \theta)^2. \]

The potential energy is

\[ V = mgl \cos \theta, \]

so that the Lagrangian is given by
\[ L = \frac{1}{2} I_1 (\dot{\theta}^2 + \dot{\phi}^2 \sin^2 \theta) + \frac{1}{2} I_3 (\dot{\psi} + \dot{\phi} \cos \theta)^2 - mgl \cos \theta. \]  
\( \quad \) (2.167)

We have

\[ p_\psi = \frac{\partial L}{\partial \dot{\psi}} = I_3 (\dot{\psi} + \dot{\phi} \cos \theta) = I_3 \omega_3 = I_1 a, \]  
\( \quad \) (2.168)

\[ p_\phi = \frac{\partial L}{\partial \dot{\phi}} = (I_1 \sin^2 \theta + I_3 \cos^2 \theta) \dot{\phi} + I_3 \dot{\psi} \cos \theta = I_1 b, \]  
\( \quad \) (2.169)

and

\[ E = T + V = \frac{1}{2} I_1 (\dot{\theta}^2 + \dot{\phi}^2 \sin^2 \theta) + \frac{1}{2} I_3 \omega_3^2 + Mgl \cos \theta. \]  
\( \quad \) (2.170)

Combining these first two expressions gives

\[ \dot{\phi} = \frac{b - a \cos \theta}{\sin^2 \theta}, \]  
\( \quad \) (2.171)

and

\[ \dot{\psi} = \frac{I_1 a}{I_3} - \cos \theta \frac{b - a \cos \theta}{\sin^2 \theta}. \]  
\( \quad \) (2.172)

### 2.3 OSCILLATORY MOTION

#### 2.3.1 Oscillations

Consider a system that is subjected to a potential that is only a function of coordinates. If we expand the coordinates \( q_i \) about their equilibrium position according to

\[ q_i = q_{i0} + \eta_i, \]  
\( \quad \) (2.173)

and then perform a Taylor series expansion on the potential we obtain
\[ V(q_i) = V(q_{i_0}) + \left( \frac{\partial V}{\partial q_i} \right)_{q_{i_0}} \eta_i + \frac{1}{2} \left( \frac{\partial^2 V}{\partial q_i \partial q_j} \right)_{q_{i_0}} \eta_i \eta_j + \ldots \] (2.174)

The first term on the right hand side may be redefined to be zero by shifting the zero potential to be the equilibrium value. Similarly, if the generalized forces are zero the second term is also zero. As a result, the potential can be approximated by the matrix relation

\[ V(q_i) \approx \frac{1}{2} \left( \frac{\partial^2 V}{\partial q_i \partial q_j} \right)_{q_{i_0}} \eta_i \eta_j. \] (2.175)

Similarly, we can define

\[ T = \frac{1}{2} m_j \ddot{q}_j \] (2.176)

so that the Lagrangian is

\[ L = \frac{1}{2} \left( T_{ij} \dot{\eta}_i \dot{\eta}_j - V_{ij} \eta_i \eta_j \right). \] (2.177)

The equations of motion are given by

\[ T_{ij} \ddot{\eta}_j + V_{ij} \eta_j = 0. \] (2.178)

If we try a solution of the form \( \eta_i = C a_i \exp^{-i\omega t} \) we find that

\[ V_{ij} a_j - \omega^2 T_{ij} a_j = 0, \] (2.179)

which is equivalent to

\[ \left| V - \omega^2 T \right| = 0. \] (2.180)

*Example 2.4*
Two particles move in one dimension at the junction of three springs as shown. The springs all have unstretched length $a$ and force constants as shown. Find the frequencies of the normal modes of oscillation.

We define the coordinates $x_1$ and $x_2$ to describe the displacement of the two blocks, relative to the left attachment point. In these coordinates

$$T = \frac{1}{2} m x_1^2 + \frac{1}{2} m x_2^2. \tag{2.181}$$

Expanding about equilibrium, we define $x_1 = a + \eta_1$, $x_2 = 2a + \eta_2$. Equation 2.181 is equivalent to

$$T = \frac{1}{2} m \eta_1^2 + \frac{1}{2} m \eta_2^2 = \frac{1}{2} T_{ij} \eta_i \eta_j, \tag{2.182}$$

where

$$T_{ij} = \begin{pmatrix} m & 0 \\ 0 & m \end{pmatrix}. \tag{2.183}$$

Similarly,

$$V = \frac{1}{2} k (x_1 - a)^2 + \frac{1}{2} 3k [x_2 - x_1 - a]^2 + \frac{1}{2} k (2a - x_2)^2, \tag{2.184}$$

or

$$V = \frac{1}{2} V_{ij} \eta_i \eta_j, \tag{2.185}$$

with

$$V_{ij} = \left. \frac{\partial^2 V}{\partial x_i \partial x_j} \right|_a. \tag{2.186}$$
By examination

\[ \frac{\partial V}{\partial x_1} = k(x_1 - a) - 3k(x_2 - x_1 - a), \quad (2.187) \]

\[ \frac{\partial^2 V}{\partial x_1^2} = k + 3k = 4k, \quad (2.188) \]

and

\[ \frac{\partial V}{\partial x_2} = 3k(x_2 - x_1 - a) - k(2a - x_2), \quad (2.189) \]

\[ \frac{\partial^2 V}{\partial x_2^2} = 3k + k = 4k. \quad (2.190) \]

Likewise, the cross terms are

\[ \frac{\partial^2 V}{\partial x_1 \partial x_2} = \frac{\partial^2 V}{\partial x_2 \partial x_1} = -3k, \quad (2.191) \]

so that

\[ V_{ij} = \begin{pmatrix} 4k & -3k \\ -3k & 4k \end{pmatrix}. \quad (2.192) \]

The secular equation is

\[ \begin{vmatrix} V - \omega^2 T \end{vmatrix} = \begin{vmatrix} 4k - \omega^2 m & -3k \\ -3k & 4k - \omega^2 m \end{vmatrix} = 0, \quad (2.193) \]

which reduces to

\[ (4k - \omega^2 m)^2 - 9k = m^2 \omega^4 - 8km \omega^2 + 7k^2 = 0. \quad (2.194) \]

From the quadratic equation, this has solutions
\[ \omega_1 = \sqrt{\frac{k}{m}}, \quad (2.195) \]

and

\[ \omega_2 = \sqrt{\frac{7k}{m}}. \quad (2.196) \]

### 2.4 Hamilton's Equations

#### 2.4.1 Legendre Transformations and Hamilton's Equations of Motion

Consider a function \( f \) of two variables such that

\[ df = u \, dx + v \, dy, \quad (2.197) \]

where \( u = \frac{\partial f}{\partial x} \) and \( v = \frac{\partial f}{\partial y} \). We wish to change from the variables \( x, y \) to the variables \( u, y \). We define a function

\[ g = f - ux. \quad (2.198) \]

We have

\[ dg = df - dux - udx = vdy - xdu, \quad (2.199) \]

so that \( x = -\frac{\partial g}{\partial u} \) and \( v = \frac{\partial g}{\partial y} \). This is an example of a Legendre transformation. It is frequently used in thermodynamics.

Recall that Lagrange's equations are

\[ \frac{d}{dt} \left( \frac{\partial L}{\partial \dot{q}_i} \right) - \frac{\partial L}{\partial q_i} = 0, \quad (2.200) \]

where \( L = L(q_i, \dot{q}_i, t) \), and the conjugate momenta are
\begin{align*}
p_i &= \frac{\partial L(q_i, \dot{q}_i, t)}{\partial \dot{q}_i}, \quad (2.201) \\

\text{We can transform from the variables } (q_i, \dot{q}_i, t) \text{ to the variables } (q_i, p_i, t) \text{ by the use of} \\

H(q_i, p_i, t) &= \dot{q}_i p_i - L(q_i, \dot{q}_i, t), \quad (2.202) \\

\text{where } H \text{ is called the Hamiltonian. We have} \\

dH = \frac{\partial H}{\partial q_i} dq_i + \frac{\partial H}{\partial p_i} dp_i + \frac{\partial H}{\partial t} dt. \quad (2.203) \\

\text{However, from the definition} \\

dH = p_i dq_i + \dot{q}_i dp_i - \frac{\partial L}{\partial q_i} dq_i - \frac{\partial L}{\partial \dot{q}_i} d\dot{q}_i - \frac{\partial L}{\partial t} dt, \quad (2.204) \\

\text{or simply} \\

dH = \dot{q}_i dp_i - \frac{\partial L}{\partial q_i} dq_i - \frac{\partial L}{\partial \dot{q}_i} d\dot{q}_i - \frac{\partial L}{\partial t} dt. \quad (2.205) \\

\text{Comparing the two expressions for } dH \text{ we obtain Hamilton's equations} \\

\frac{\partial H}{\partial q_i} = - \frac{\partial L}{\partial q_i} = - \dot{p}_i, \quad (2.206) \\

\frac{\partial H}{\partial p_i} = \dot{q}_i, \quad (2.207) \\

\frac{\partial H}{\partial t} = - \frac{\partial L}{\partial t}. \quad (2.208) \\

\text{If the equations defining the generalized coordinates don't depend on time explicitly, and if the forces are derivable from a conservative potential } V, \text{ then} \\

H = T + V = E. \quad (2.209)
\end{align*}
If we define a column matrix \( \dot{\eta} \) with 2n elements such that \( \eta_i = q_i \), \( \eta_{i+n} = p_i \), for \( i \leq n \), then

\[
\left( \frac{\partial H}{\partial \eta_i} \right) = \frac{\partial H}{\partial q_i},
\]

(2.210)

and

\[
\left( \frac{\partial H}{\partial \eta_{i+n}} \right) = \frac{\partial H}{\partial p_i}.
\]

(2.211)

If we define \( \bar{J} = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \), then Hamilton's equations may be written in the form

\[
\dot{\eta} = \bar{J} \frac{\partial H}{\partial \dot{\eta}}.
\]

(2.212)

This is called symplectic notation.

**Example 2.5**

The Lagrangian for a simple spring is given by

\[
L = \frac{1}{2} m \dot{x}^2 - \frac{1}{2} k x^2.
\]

Find the Hamiltonian and the equations of motion using the Hamiltonian formulation. Identify any conserved quantities.

From the definition of \( p_i \) we have

\[
p_x = \frac{\partial L}{\partial \dot{x}} = m \dot{x}.
\]

(2.213)

From the definition of the Hamiltonian, equation 2.227, we see that

\[
H = \dot{x}(m \dot{x}) - \frac{1}{2} m \dot{x}^2 + \frac{1}{2} k x^2.
\]

(2.214)
or simply

\[ H = \frac{1}{2m} p_x^2 + \frac{1}{2} k x^2. \]  

(2.215)

From Hamilton's equations we have

\[ \frac{\partial H}{\partial q_i} = k x = -\dot{p}_x, \]  

(2.216)

\[ \frac{\partial H}{\partial p_i} = \frac{p_x}{m} = \dot{x}, \]  

(2.217)

\[ \frac{\partial H}{\partial t} = 0. \]  

(2.218)

The first equation is the equation of motion in one dimension,

\[ m \ddot{x} + k x = 0, \]  

(2.219)

the second equation is the definition of momentum, and the last equation is the statement of conservation of energy.

### 2.5.2 Canonical Transformations

If a generalized coordinate \( q_i \) has constant conjugate momenta it is said to be cyclic. If this is the case, then \( p_i = 0 \), which tells us that the Hamiltonian is independent of that \( p_i \). If all coordinates \( q_i \) are cyclic the conjugate momenta can be defined by \( p_i = \alpha_i \). Consequently,

\[ q_i = \frac{\partial H}{\partial \alpha_i} = \omega_i, \]  

(2.220)

or

\[ q_i = \omega_i t + \dot{\beta}_i. \]  

(2.221)

A problem is often easier to solve if we can find a system where the number of cyclic coordinates is maximum. How do we transform to this set of
coordinates? We need a new set of coordinates \( Q_i, P_i \), where \( Q_i = Q_i(q_i, p_i, t) \), 
\( P_i = P_i(q_i, p_i, t) \). We require \( Q_i, P_i \) to be canonical coordinates. Therefore, 
some function \( K = K(Q_i, P_i, t) \) exists such that 

\[
\dot{Q}_i = \frac{\partial K}{\partial P_i},
\]

(2.222)

and

\[
\dot{P}_i = \frac{\partial K}{\partial Q_i}.
\]

(2.223)

If \( Q_i, P_i \) are canonical coordinates they must satisfy a modified Hamilton's 
principle that can be put in the form

\[
\delta \int_{t_1}^{t_2} \left( P_i \dot{Q}_i - K(Q_i, P_i, t) \right) dt = 0,
\]

(2.224)

because the old coordinates satisfy

\[
\delta \int_{t_1}^{t_2} \left( p_i \dot{q}_i - H(q_i, p_i, t) \right) dt = 0.
\]

(2.225)

Both requirements can be satisfied if we require a relation

\[
\lambda (p_i \dot{q}_i - H) = P_i \dot{Q}_i - K + \frac{dF}{dt},
\]

(2.226)

where \( \lambda = \text{constant} \) and \( F \) is any function of the phase space coordinates 
continuous through the second derivative. \( \lambda \) is related to a scale 
transformation. If \( \lambda = 1 \) the relation defines a canonical transformation. The 
function \( F \) is termed the generating function. It may be a function of \( q_i, p_i, Q_i, 
P_i, t \) and defines the transformation.

2.5.3 Symplectic Transformations and Poisson Brackets
Recall that Hamilton's equations can be written in the form

\[ \dot{\eta} = \mathbf{J} \frac{\partial H}{\partial \eta}. \] (2.227)

If we have a canonical transformation from \( \eta \rightarrow \xi = \xi(\eta) \), then

\[ \dot{\xi}^i = \frac{\partial \xi^i}{\partial \eta^j} \dot{\eta}^j. \] (2.228)

In matrix form,

\[ \dot{\xi} = \mathbf{M} \dot{\eta}. \] (2.229)

where \( M_{ij} = \frac{\partial \xi^i}{\partial \eta^j} \). We have

\[ \dot{\xi} = \mathbf{M} \dot{\eta}. \] (2.230)

also

\[ \frac{\partial H}{\partial \eta^i} = \frac{\partial H}{\partial \xi^j} \frac{\partial \xi^j}{\partial \eta^i}. \] (2.231)

and

\[ \frac{\partial H}{\partial \eta} = \mathbf{M} \frac{\partial H}{\partial \xi}. \] (2.232)

Consequently,

\[ \dot{\xi} = \mathbf{M} \dot{\eta}. \] (2.233)

Therefore, a transformation is canonical if

\[ \mathbf{M} \mathbf{M}^T = \mathbf{J}. \] (2.234)
The Poisson bracket of a function is defined by
\[
[u, v]_{PB} = \frac{\partial u}{\partial q_i} \frac{\partial v}{\partial p_i} - \frac{\partial u}{\partial p_i} \frac{\partial v}{\partial q_i}.
\] (2.235)

We have

\[
[\tilde{\eta}, \tilde{\eta}]_{PB} = \tilde{J},
\] (2.236)

and

\[
\left[ \tilde{\xi}, \tilde{\xi} \right]_{PB} = \frac{\partial \tilde{\xi}}{\partial \tilde{\eta}} \frac{\partial \tilde{\xi}}{\partial \tilde{\eta}} = \tilde{M} \tilde{M} = \tilde{J}.
\] (2.237)

In other words, the fundamental Poisson brackets are invariant under canonical transformations. We also have

\[
\frac{du}{dt} = \frac{\partial u}{\partial q_i} \dot{q}_i + \frac{\partial u}{\partial p_i} \dot{p}_i + \frac{\partial u}{\partial t},
\] (2.238)

or

\[
\frac{du}{dt} = [u, H]_{PB} + \frac{\partial u}{\partial t}.
\] (2.239)

Similarly,

\[
\dot{q}_i = [q_i, H]_{PB}, \quad \dot{p}_i = [p_i, H]_{PB}.
\] (2.240)

### 2.6 CONTINUOUS SYSTEMS

#### 2.6.1 The Transition from a Discrete to a Continuous System

Consider an infinitely long elastic rod that can undergo small longitudinal vibrations. We approximate this by an infinite chain of equal mass points a distance \(a\) apart and connected by uniform massless springs having force constraints \(k\). The kinetic energy is
\[ T = \frac{1}{2} \sum_i m \eta_i^2, \]  

(2.241)

where \( m \) is the mass of each particle and \( \eta_i \) is the location of the \( i \)th particle.
The potential energy is

\[ V = \frac{1}{2} \sum_k k (\eta_{i+1} - \eta_i)^2. \]  

(2.242)

We have

\[ L = \frac{1}{2} \sum_i \left[ m \eta_i^2 - k (\eta_{i+1} - \eta_i)^2 \right]. \]  

(2.243)

or

\[ L = \frac{1}{2} \sum_i \left[ \frac{m}{2} \eta_i^2 - ka \left( \frac{\eta_{i+1} - \eta_i}{a} \right)^2 \right]. \]  

(2.244)

The equations of motion are

\[ \frac{m}{a} \ddot{\eta}_i - ka \left( \frac{\eta_{i+1} - \eta_i}{a} \right) + ka \left( \frac{\eta_i - \eta_{i-1}}{a} \right) = 0. \]  

(2.245)

We have \( m/a = \mu = \text{mass/unit length} \). Hooke’s law states that the extension of a rod/unit length is proportional to the force, i.e.

\[ F = Y \xi, \]  

(2.246)

where \( \xi = \left( \frac{\eta_{i+1} - \eta_i}{a} \right) \) is the extension/unit length. The force necessary to stretch the string by an amount \( x \) is

\[ F = k (\eta_{i+1} - \eta_i) = ka \left( \frac{\eta_{i+1} - \eta_i}{a} \right). \]  

(2.247)

Consequently, \( ka = Y = \text{Young’s modulus} \). Note that
\[
\frac{\eta_{i+1} - \eta_i}{a} = \frac{\eta(x + a) - \eta(x)}{a} \rightarrow \frac{d\eta}{dx}, \tag{2.248}
\]

as \( a \rightarrow 0 \). Also as \( a \rightarrow 0 \) the summation over the particles becomes an integral and Equation 2.244 becomes

\[
L = \frac{1}{2} \int \mu \eta^2 - Y \left( \frac{d\eta}{dx} \right)^2 dx. \tag{2.249}
\]

The equation of motion is

\[
\mu \frac{d^2 \eta}{dt^2} - Y \frac{d^2 \eta}{dx^2} = 0. \tag{2.250}
\]

This is a wave equation with wave propagation velocity \( v = \sqrt{\frac{Y}{\mu}} \). Equation 2.249 is said to define a Lagrangian density

\[
\tilde{L} = \mu \left( \frac{d\eta}{dt} \right)^2 - Y \left( \frac{d\eta}{dx} \right)^2. \tag{2.251}
\]

### 2.6.2 The Lagrangian Formulation

Consider a Lagrangian density

\[
\tilde{L} = \tilde{L}\left( \eta, \frac{d\eta}{dx}, \frac{d\eta}{dt}, x, t \right). \tag{2.252}
\]

Hamilton's principle is

\[
\delta \tilde{L} = \delta \int_{1}^{2} \tilde{L} dx dt = 0. \tag{2.253}
\]

We choose value of \( \eta \) such that

\[
\eta(x, t; \alpha) = \eta(x, t; 0) + \alpha \zeta(x, t), \tag{2.254}
\]
where \( \eta(x,t;0) \) is the function that satisfies Hamilton's principle. We have

\[
\delta I = \left( \frac{d\alpha}{d\xi} \right)_{\xi = 0} = 0, \tag{2.255}
\]

where

\[
\frac{d\alpha}{d\xi} = \int_{x_1}^{x_2} \int_{t_1}^{t_2} \left\{ \frac{\partial L}{\partial \eta} \frac{\partial}{\partial t} \left( \frac{\partial \eta}{\partial \alpha} \right) + \frac{\partial L}{\partial \eta} \frac{\partial}{\partial x} \left( \frac{\partial \eta}{\partial \alpha} \right) + \frac{\partial L}{\partial \eta} \frac{\partial}{\partial t} \left( \frac{\partial \eta}{\partial \alpha} \right) \right\} dt. \tag{2.256}
\]

This expression may be simplified as follows. First,

\[
\int_{t_1}^{t_2} \frac{d}{dt} \left( \frac{\partial L}{\partial \eta} \frac{\partial}{\partial t} \left( \frac{\partial \eta}{\partial \alpha} \right) \right) = -\int_{t_1}^{t_2} \frac{d}{dt} \left( \frac{\partial L}{\partial \eta} \frac{\partial}{\partial t} \left( \frac{\partial \eta}{\partial \alpha} \right) \right), \tag{2.257}
\]

plus a boundary term that goes to zero. Also,

\[
\int_{x_1}^{x_2} \frac{d}{dx} \left( \frac{\partial L}{\partial \eta} \frac{\partial}{\partial x} \left( \frac{\partial \eta}{\partial \alpha} \right) \right) = -\int_{x_1}^{x_2} \frac{d}{dx} \left( \frac{\partial L}{\partial \eta} \frac{\partial}{\partial x} \left( \frac{\partial \eta}{\partial \alpha} \right) \right), \tag{2.258}
\]

plus another boundary term that goes to zero. Therefore,

\[
\delta I = \int_{t_1}^{t_2} \int_{x_1}^{x_2} \left[ \frac{\partial L}{\partial \eta} \frac{\partial}{\partial t} \left( \frac{\partial \eta}{\partial \alpha} \right) - \frac{\partial L}{\partial \eta} \frac{\partial}{\partial x} \left( \frac{\partial \eta}{\partial \alpha} \right) \right] dt = 0, \tag{2.259}
\]

and
\[
\frac{d}{dt} \left( \frac{\partial \tilde{L}}{\partial (\frac{d\eta}{dx})} \right) + \frac{d}{dx} \left( \frac{\partial \tilde{L}}{\partial (\frac{d\eta}{dt})} \right) - \frac{\partial \tilde{L}}{\partial \eta} = 0. \tag{2.260}
\]

Similarly for other Lagrangians.

### 2.6.3 Noether's Theorem

A formal description of the connection between invariance or symmetry properties and conserved quantities is contained in Noether's theorem. We consider transformations where

\[
x_\mu \rightarrow x'_\mu = x_\mu + \delta x_\mu, \tag{2.261}
\]

\[
\eta_p(x_\mu) \rightarrow \eta'_p(x'_\mu) = \eta_p(x_\mu) + \eta_p(\delta x_\mu), \tag{2.262}
\]

\[
\tilde{L}(\eta_p(x_\mu), \eta_{p,v}(x_\mu), x_\mu) \rightarrow \tilde{L}(\eta'_p(x'_\mu), \eta'_{p,v}(x'_\mu), x'_\mu). \tag{2.263}
\]

We make three assumptions:

1.) 4-space is Euclidean,

2.) The Lagrangian density has the same functional form after transformation,

3.) The magnitude of the action integral is invariant under the transformation.

From assumptions 2, 3 we have

\[
\int_{\Omega} \tilde{L}(\eta'_p, \eta'_{p,v}, x'_\mu) dx'_\mu - \int_{\Omega} \tilde{L}(\eta_p, \eta_{p,v}, x_\mu) dx_\mu = 0. \tag{2.264}
\]

\(x'_\mu\) is a dummy variable, so let \(x'_\mu \rightarrow x_\mu\) to obtain
\[ \int_{\Omega'} \tilde{L}(\eta^\prime, x_\mu) \, dx_\mu - \int_{\Omega} \tilde{L}(\eta, x_\mu) \, dx_\mu = 0. \] (2.265)

Under the transformations the first order difference between the integrals consists of two parts, one is an integral over \( \Omega \) and the other is an integral over \( \Omega' - \Omega \). For example, in one dimension,

\[
\int_{a+\delta a}^{b} [f(x) + \delta f(x)] \, dx - \int_{a}^{b} f(x) \, dx = \int_{a}^{b} \delta f(x) \, dx + \int_{a}^{b} [f(x) + \delta f(x)] \, dx - \int_{a}^{b} [f(x) + \delta f(x)] \, dx.
\] (2.266)

To first order, the last two terms are

\[
\int_{b+\delta b}^{b} f(x) \, dx - \int_{a+\delta a}^{a} f(x) \, dx = \delta bf(b) - \delta af(a).
\] (2.267)

The difference between integrals is

\[
\int_{b}^{b} \delta f(x) \, dx + f(x) \delta x|^b_a = \int_{a}^{b} \left[ \delta f(x) + \frac{d}{dx} (\delta x f(x)) \right] \, dx.
\] (2.268)

Consequently, for the Lagrangians we have

\[
\int_{\Omega'} \tilde{L}(\eta^\prime, x_\mu) \, dx_\mu - \int_{\Omega} \tilde{L}(\eta, x_\mu) \, dx_\mu = \int_{\Omega'} \left[ \tilde{L}(\eta^\prime, x_\mu) - \tilde{L}(\eta, x_\mu) \right] \, dx_\mu + \int_{S} \tilde{L}(\eta) \delta x_\mu \, dS_\mu = 0.
\] (2.269)

or

\[
\int_{\Omega} d x_\mu \left[ \left[ \tilde{L}(\eta^\prime, x_\mu) - \tilde{L}(\eta, x_\mu) \right] + \frac{d}{dx_\mu} \left( \tilde{L}(\eta, x_\mu) \delta x_\mu \right) \right] = 0.
\] (2.270)

To first order,
\[ \dot{L}(\eta', x_\mu) - \dot{L}(\eta, x_\mu) = \frac{\partial \bar{L}}{\partial \eta_\rho} \bar{\delta \eta_\rho} + \frac{\partial \bar{L}}{\partial \eta_{\rho, v}} \bar{\delta \eta_{\rho, v}}, \] (2.271)

or

\[ \ddot{L}(\eta', x_\mu) - \dot{L}(\eta, x_\mu) = \frac{d}{dx_v} \left( \frac{\partial \bar{L}}{\partial \eta_{\rho, v}} \bar{\delta \eta_\rho} \right). \] (2.272)

The invariance condition is

\[ \int dx_\mu \frac{d}{dx_v} \left[ \frac{\partial \bar{L}}{\partial \eta_{\rho, v}} \bar{\delta \eta_\rho} + \dot{L} \bar{\delta x_v} \right] = 0. \] (2.273)

We define

\[ \delta x_v = \varepsilon_r X_{\rho}, \ \delta \eta_\rho = \varepsilon_r \Psi_{\rho}, \] (2.274)

because

\[ \eta_\rho' (x_\mu') = \eta_\rho (x_\mu) + \bar{\delta \eta_\rho} (x_\mu). \] (2.275)

and

\[ \delta \eta_\rho = \bar{\delta \eta_\rho} + \frac{\partial \eta_\rho}{\partial x_\sigma} \delta x_\sigma. \] (2.276)

we have

\[ \bar{\delta \eta_\rho} = \varepsilon_r \left( \Psi_{\rho} - \eta_{\rho, \sigma} X_{\sigma} \right). \] (2.277)

Equation 2.305 reduces to

\[ \int e_r \frac{d}{dx_v} \left[ \left( \frac{\partial \bar{L}}{\partial \eta_{\rho, v}} \eta_{\rho, \sigma} - \bar{L} \delta \eta_{\sigma} \right) X_{\sigma} - \frac{\partial \bar{L}}{\partial \eta_{\rho, v}} \Psi_{\rho} \right] (dx_\mu) = 0. \] (2.278)
The result is Noether's theorem, which states that
\[
\frac{d}{dx} \left( \left( \frac{\partial \tilde{L}}{\partial \eta_{\rho,\nu}} \eta_{\rho,\sigma} - \tilde{L} \delta_{\nu\sigma} \right) \chi_{\sigma} - \frac{\partial \tilde{L}}{\partial \eta_{\rho,\nu}} \Psi_{\rho} \right) = 0 . \quad (2.279)
\]

2.7 Bibliography
